augment

A fast and general method for building augmented data

Description

A fast and general method for reshaping standard longitudinal data into a new structure called augmented'. This format is suitable under a multi-state framework using the msm package.

Usage

```
augment(
  data,
  data_key,
  n_events,
  pattern,
  state = list("IN", "OUT", "DEAD"),
  t_start,
  t_end,
  t_cens,
  t_death,
  t_augmented,
 more_status,
  check_NA = FALSE,
 convert = FALSE,
  verbose = TRUE
)
```

Arguments

data

A data.table or data.frame object in longitudinal format where each row represents an observation in which the exact starting and ending time of the process are known and recorded. If data is a data.frame, then augment internally casts it to a data.table.

data_key

A keying variable which augment uses to define a key for data. This represents the subject ID (see setkey).

n_events

An integer variable indicating the progressive (monotonic) event number of a given ID. augment always checks whether n_events is monotonic increasing within the provided data_key and stops the execution in case the check fails (see 'Details'). If missing, augment fastly creates a variable named "n_events".

augment 3

pattern Either an integer, a factor or a character with 2 or 3 unique values which provides the ID status at the end of the study. pattern has a predefined structure. When 2 values are detected, they must be in the format: 0 = "alive", 1 = "dead". When 3 values are detected, then the format must be: 0 = "alive", 1 = "dead during atransition", 2 = "dead after a transition has ended" (see 'Details'). state A list of three and exactly three possible states which a subject can reach. state has a predefined structure as follows: IN, OUT, DEAD (see 'Details'). The starting time of an observation. It can be passed as date, integer, or numeric t_start t_end The ending time of an observation. It can be passed as date, integer, or numeric format. t_cens The censoring time of the study. This is the date until each ID is observed, if still active in the cohort. t_death The exact death time of a subject ID. If t_death is missing, t_cens is assumed to contain both censoring and death times and a warning is raised. t_augmented A variable indicating the name of the new time variable of the process in the augmented format. If t_augmented is missing, then the default name 'augmented' is assumed and the corresponding new variable is added to data. t_augmented is cast to integer or to numeric depending whether t_start is a date or a difftime, respectively. The suffix '_int' or '_num' is pasted to t_augmented and a new variable is computed accordingly. This is done because msm can't correctly deal with date or difftime variables. Both variables are positioned before t_start. more_status A variable which marks further transitions beside the default ones given by state. more_status can be a factor or a character (see 'Details'). If missing, augment ignores it. check_NA If TRUE, then arguments data_key, n_events, pattern, t_start and t_end are looked up for any missing data and if the function finds any, it stops with error. Default is FALSE because augment is not intended for running consistency checks, beside what is mandatory, and because the procedure is computationally onerous and could cause memory overhead for very large datasets. Argument more_status is the only one for which augment always checks for the presence of missing data and, again, if it finds any it just stops with error. convert If TRUE, then the returned object is automatically converted to the class data. frame. This is done in place and comes at very low cost both from running time and memory consumption (see setDF). verbose If FALSE, all information produced by print, cat and message are suppressed. Default is TRUE.

Details

In order to get the data processed, a monotonic increasing process needs to be ensured. In the first place, augment checks this both in case n_events is missing or not. The data are efficiently ordered through setkey function with data_key as the primary key and t_start as the secondary key. In the second place, it checks the monotonicity of n_events and if it fails, it stops with error and returns the subjects given by data_key for whom the condition is not met. If n_events is missing,

4 augment

then augment internally computes the progression number with the name n_events and runs the same procedure.

Attention needs to be payed to argument pattern. Integer values can be 0 and 1 if only two status are defined and they must correspond to the status 'alive' and 'dead'. If three values are defined, then they must be 0, 1 and 2 if pattern is an integer, or 'alive', 'dead inside a transition' and dead outside a transition' if pattern is either a character or a factor. The order matters: it is not possible to specify 0 as 'dead' for instance.

When passing a list of states, the order is important so that the first element must be the state corresponding to the starting time (i.e. 'IN', inside the hospital), the second element must correspond to the ending time (i.e. 'OUT', outside the hospital), and the third state is the absorbing state (i.e. 'DEAD').

more_status allows to manage multiple transitions beside what already specified in state. In particular, if the corresponding observation is a standard admission which adds no other information than what is inside state, then more_status must be set to 'df' which stands for 'Default' (see 'Examples' or run 'hosp and look at the variable 'rehab_it'). In general, it is always a good practice to fully specify the transition with a bunch of self-explanatory characters in order to quickly understand which is the current transition.

Value

An augmented format dataset of class data.table, or data.frame when convert is TRUE, where each row represents a specific transition for a given subject. augment returns them after some important variables have been computed:

augmented	The new timing variable for the process when looking at transitions. If t_augmented is missing, then augment creates <i>augmented</i> by default. <i>augmented</i> . The function looks directly to t_start and t_end to build it and thus it inherits their class. In particular, if t_start is a date format, then augment computes a new variable cast as integer and names it <i>augmented_int</i> . If t_start is a difftime format, then augment computes a new variable cast as a numeric and names it <i>augmented_num</i> .
status	A status flag which contains the states as specified in state. augment automatically checks whether argument pattern has 2 or 3 unique values and computes the correct structure of a given subject as reported in the vignette. The variable is cast as character.
status_num	The corresponding integer version of status.
n_status	A mix of status and n_events cast as character. This becomes useful when a multi-state model on the progression of the process needs to be implemented.

If more_status is passed, then augment computes some more variables. They mimic the meaning of *status*, *status_num*, and *n_status* but they account for the more complex structure defined. They are: status_exp_ status_exp_num, and n_status_exp.

hosp

Synthetic Hospital Admissions

Description

A dataset containing synthetic hospital admissions in the classic longitudinal format. The dataset counts imaginary 10 patients who undergo different (re)admission into a hospital. Some demographic and clinical variables are also included.

6 msmtools

Usage

hosp

Format

```
A data. table with 53 rows and 12 variables:
```

subj Subject ID (integer)

adm number Hospital admissions counter (integer)

gender Gender of patient (factor with 2 levels: "F" = females, "M" = males)

age Age of patient in years at the given observation (integer)

rehab Rehabilitation flag: if the admission has been in rehabilitation, then rehab = 1, else = 0 (integer)

it Intensive Therapy flag: if the admission has been in intensive therapy, then it = 1, else = 0 (integer)

rehab_it String which in one place marks the hospital admission types based on rehab and it. The standard admission is coded as "df" (default). If admission was in rehabilitation or in intensive therapy, rehab_it = "rehab" or "it", respectively (character)

label_2 Subject status at the end of the study. It takes 2 values: "alive" and "dead" (character)

label_3 Subject status at the end of the study. It takes 3 values: "alive" and "dead_in" and "dead_out" (character)

dateIN Exact admission date (date)

dateOUT Exact discharge date (date)

dateCENS Either censoring time or exact death time (date)

msmtools

Building augmented data for multi-state models: the msmtools package

Description

msmtools introduces a fast and general method for restructuring classical longitudinal datasets into *augmented* ones. Augmented data enhances longitudinal datasets and allow to model each transition under a multi-state framework. msmtools works in symbiosis with the msm package. It also provides two graphical goodness-of-fit tools to inspect the model performances using survival curves and prevalences under the Markov assumption. msmtools comes with 4 functions: augment, polish, prevplot, and survplot.

polish 7

_			
no1	i	c	h
1301			

Remove observations with different states occurring at the same time

Description

Fast algorithm to get rid of transitions to different states occurring at the same exact time in an augmented data structure as computed by augment (see 'Details').

Usage

```
polish(
  data,
  data_key,
  pattern,
  time,
  check_NA = FALSE,
  convert = FALSE,
  verbose = TRUE
)
```

Arguments

data	A data.table or data.trame object in longitudinal format where each row
	represents an observation in which the exact starting and ending time of the pro-

cess are known and recorded. If data is a data. frame, then augment internally

casts it to a data.table.

data_key A keying variable which augment uses to define a key for data. This represents

the subject ID (see setkey).

pattern Either an integer, a factor or a character with 2 or 3 unique values which provides

the ID status at the end of the study. pattern has a predefined structure. When 2 values are detected, they must be in the format: 0 = "alive", 1 = "dead". When 3 values are detected, then the format must be: 0 = "alive", 1 = "dead during a limits

transition", 2 = "dead after a transition has ended" (see 'Details').

time The target time variable to check duplicates. By default it is set to 'augmented_int'.

check_NA If TRUE, then arguments data_key, pattern, and time are looked up for any

missing data and if the function finds any, it stops with error. Default is FALSE.

convert If TRUE, then the returned object is automatically converted to the class data. frame.

This is done in place and comes at very low cost both from running time and

memory consumption (see setDF).

verbose If FALSE, all information produced by print, cat and message are suppressed.

Default is TRUE.

8 prevplot

Details

The function finds all those cases where two subsequent events for a given subject land on different states but occur at the same time. When this happens, the whole subject, as identified by data_key, is removed from the data. The total number of subjects to be removed is printed out in order to be more informative.

Examples

prevplot

Plot observed and expected prevalences for a multi-state model

Description

Provides a graphical indication of goodness of fit of a multi-state model computed by msm using observed and expected prevalences. It also computes a rough indicator of where the data depart from the estimated Markov model.

Usage

```
prevplot(x, prev.obj, exacttimes = TRUE, M = FALSE, ci = FALSE)
```

Arguments

x A msm object.

prev.obj A list computed by prevalence.msm. It can be with or without confidence intervals. prevplot will behaves accordingly.

exacttimes If TRUE (default) then transition times are known and exact. This is inherited from msm and should be set the same way.

prevplot 9

M If TRUE, then a rough indicator of deviance from the model is computed (see 'Details'). Default is FALSE.

ci If TRUE, then confidence intervals, if they exist, are plotted. Default is FALSE.

Details

When M = TRUE, a rough indicator of the deviance from the Markov model is computed according to Titman and Sharples (2008). A comparison at a given time t_i of a patient k in the state s between observed counts O_{is} with expected ones E_{is} is build as follows:

$$M_{is} = \frac{(O_{is} - E_{is})^2}{E_{is}}$$

The plot of the deviance M is returned together with the standard prevalence plot in the second row. This is not editable by the user.

## End(Not run)
```

survplot

Plot and get survival data from a multi-state model

Description

Plot the fitted survival probability computed over a msm model and compare it with the Kaplan-Meier. Fast build and return the underlying data structures.

Usage

```
survplot(
    x,
    from = 1,
    to = NULL,
    range = NULL,
    covariates = "mean",
    exacttimes = TRUE,
    times,
```

```
grid = 100L,
km = FALSE,
out = c("none", "fitted", "km", "all"),
ci = c("none", "normal", "bootstrap"),
interp = c("start", "midpoint"),
B = 100L,
ci_km = c("none", "plain", "log", "log-log", "logit", "arcsin")
```

Arguments

out

x A msm object.

from State from which to compute the estimated survival. Default to state 1.

to The absorbing state to which compute the estimated survival. Default to the

highest state found by absorbing.msm.

range A numeric vector of two elements which gives the time range of the plot.

covariates Covariate values for which to evaluate the expected probabilities. These can

either be: the string "mean", denoting the means of the covariates in the data (default), the number 0, indicating that all the covariates should be set to zero,

or a list of values, with optional names. For example:

list (75, 1)

where the order of the list follows the order of the covariates originally given in

the model formula, or a named list: list (age = 75, gender = "M").

exacttimes If TRUE (default) then transition times are known and exact. This is inherited

from msm and should be set the same way.

times An optional numeric vector giving the times at which to compute the fitted sur-

vival.

An integer specifying the grid points at which to compute the fitted survival (see

'Details'). If times is passed, grid is ignored. Default to 100 points.

km If TRUE, then the Kaplan-Meier curve is plotted. Default is FALSE.

A character vector specifying what the function has to return. Accepted values

are "none" (default) to return just the plot, "fitted" to return the fitted survival curve only, "km" to return the Kaplan-Meier only, "all" to return all of the

above.

ci A character vector with the type of confidence intervals to compute for the fitted survival curve. Specify either "none" (default), for no confidence intervals, "normal" or "bootstrap", for confidence intervals computed with the respec-

tive method in pmatrix.msm. This is very computationally-intensive, since in-

tervals must be computed at a series of times.

interp If "start" (default), then the entry time into the absorbing state is assumed to be the time it is first observed in the data. If "midpoint", then the entry time into the absorbing state is assumed to be halfway between the time it is first observed and the previous observation time. This is generally more reasonable

for "progressive" models with observations at arbitrary times.

В	Number of bootstrap or normal replicates for the confidence interval. The de-
	fault is 100 rather than the usual 1000, since these plots are for rough diagnostic
	purposes.

ci_km A character vector with the type of confidence intervals to compute for the Kaplan-Meier curve. Specify either "none", "plain", "log", "log-log", "logit", or "arcsin", as coded in survfit.

Details

The function is a wrapper of plot.survfit.msm and does more things. survplot manages correctly the plot of a fitted survival in an exact times framework (when exacttimes = TRUE) by just resetting the time scale and looking at the follow-up time. It can quickly build and return to the user the data structures used to compute the Kaplan-Meier and the fitted survival probability by specifying out = "all".

The user can defined custom times (through times) or let survplot choose them on its own (through grid). In the latter case, survplot looks for the follow-up time and divides it by grid. The higher it is, the finer the grid will be so that computing the fitted survival will take longer, but will be more precise.

Value

When out = "none", a gg/ggplot object is returned. If out is anything else, then a named list is returned. The Kaplan-Meier data can be accessed with \$km while the estimated survival data with \$fitted. If out = "all", the plot, the Kaplan-Meier and the estimated curve are returned.
